

Finding and Exporting Data

Not sure what tool to use to find and export data? BioMart is used to retrieve data for complex queries, involving a few or many genes or even complete genomes.

BioMart

Answer key

Contents

1. BioMart basics
2. How to use the tool and interpret its output?
 - a. Quick start
 - b. Five sample queries:
 - How to export sequence of your genes of interest?
 - How to find all the homolog genes for your family of interest?
 - How to find protein-coding genes with transmembrane domains?
 - List of orthologous genes between two species
 - How to join two different datasets?
3. Questions and practice exercises
 - a. Gene content - using “Filters”: number of genes on a specific genomic location, gene type, query with a list of genes
 - b. Gene information - defining “Attributes” : **gene characteristics (symbol and function), Gene Ontology enrichment**, genes with PubMed IDs, protein domains, ortholog assignments
 - c. Other outputs - Attributes → Sequences: gene sequence
 - d. Advanced Practice Exercises: gene type (protein-coding) -> specific genomic location -> homology relationships (orthologous), **download splice variant sequences for a specific gene**

1. BioMart basics

BioMart is a biological data mining tool. It allows users to look up specific data of different types using a user friendly interface, just with a few click you can perform complex queries

across organisms. In brief, to set up a query you need to apply “Filters” and declare “Attributes”, which are the reported data fields. The results can be visualized on screen and also downloaded in different file formats, e.g., HTML, XLS. To call the script, in addition to the web graphical user interface (GUI), you can also use web services, Perl API and the URL.

These are the different data types available from BioMart¹:

Genes: gene metadata, predicted molecular and bioinformatic information, sequences

Variation: Single Nucleotide Polymorphisms, SNPs

Expression: Transcript data

2. How to use the tool and interpret its output?

a. Quick start

Go to BioMart (from the Tools navigation menu or from the organism pages)

Choose the Genes database

Select *Anopheles gambiae* dataset (or gene set)

Perform a query selecting “Filters” to ask for protein-coding genes:

- Filters -> gene -> gene type -> protein_coding

¹ BioMart Genes database works with all VectorBase genomes except with *Anopheles sinensis* (China) and *An. stephensi* (Indian). Based on data availability, only a subset of specie is available for the Variation and Expression databases.

- Click on “Count” (gives total of hits) and on “Results” (shown the hits). Notice that out of the 13763 genes in the genome of *Anopheles gambiae*, 13024 are coding genes. By default the table shows only 10.

- Refine your query with an ID list. Filters -> gene -> Input external references ID list (type, paste or upload file): AGAP013149, AGAP012985, AGAP012982, AGAP001162, AGAP001161, AGAP002462, AGAP006126, AGAP010089, AGAP007548, AGAP002443, AGAP002444

Select “[Attributes](#)” to obtain the following gene metadata

- Attributes -> Features -> Gene -> Ensembl -> Gene name -> Gene description

Click on ‘Count’ and ‘Results’

Export results to -> File -> XLS -> GO

Gene stable ID	Transcript stable ID	Gene name	Gene description
AGAP001161	AGAP001161-RA	GPROP6	long wavelength sensitive opsin [Sou

b. Sample queries

Sample query #1

How to export sequence of your genes of interest?

1. Create a text file (*.txt) with these gene ID's: AGAP001856, AGAP008288, AGAP004261, AGAP006376, AGAP005655. A sample file provided in the tutorial's page.

2. Go to BioMart.

3. Choose “Genes” as your DataBase and *A. gambiae* as your “Dataset”.
4. Click on “Filters” -> Gene
5. Click on the check box for “Input external references ID list”. By default you get “Gene stable ID(s)” in the drop down menu. Click on “Choose File” and upload the text file from step 1 or type/copy the gene IDs in the box provided.
6. Click on “Attributes” -> Sequences -> SEQUENCES
7. Select “cDNA sequences”.
8. Click on “Count” and later on “Results”. You have selected 5 out of the 13,763 *A. gambiae* genes.
9. By default the output is in FASTA format. Click on “Go” to download the results.

The screenshot shows the BioMart interface. On the left, the 'Dataset 5 / 13763 Genes' section is highlighted. Under 'Filters', 'Gene stable ID(s) [e.g. AGAP000002]: [ID-list specified]' is selected. Under 'Attributes', 'cDNA sequences' is selected. On the right, the 'Export all results to' dropdown is set to 'File', and the 'FASTA' format is selected. The 'Go' button is highlighted. Below the export options, the 'View' section shows '10 rows as FASTA Unique results only'. The main content area displays a FASTA sequence for AGAP006376, starting with >AGAP006376 | AGAP006376-RB and followed by the sequence ATGAACATGGAATTCCAACCCCTTGCCGCGGTGTCGACGATGAACATTGGGCCAC...

Sample query #2

How to find all the homolog genes for your family of interest?

1. Go to BioMart. Choose genes as your database and *A. aegypti* as your dataset.
2. Click on Filters and expand the “Protein domains and families” section. Check the box “Limit to genes with these family or domain IDs”, select InterPro ID(s) and type “IPR004117”² in the provided box.

² You can obtain this information in the Genome Browser from your gene of interest under Transcript-based displays > Domains & features. Use the InterPro accession in the InterPro website, <https://www.ebi.ac.uk/interpro/>. IPR004117 comes back as “Olfactory receptor, insect”.

- Click on Attributes and select Features -> GENE -> Ensembl -> Chromosome/scaffold name, gene start (bp), gene end (bp), gene name, and gene description.
- Click on “Count” and “Results”. There are 122 genes with this “Olfactory receptor, insect” protein domain in *A. aegypti* genome.
- Export the file XLS format.

Sample query #3

How to find protein-coding genes with transmembrane domains?

- Go to BioMart. Choose genes as your database and *Culex quinquefasciatus* as your dataset.
- Select the filters
 - GENE -> Gene type -> protein_coding
 - PROTEIN DOMAINS AND FAMILIES -> Limit to genes with these family or domain IDs -> InterPro ID(s): IPR017452³
- Select attributes
 - GENE -> Ensembl -> Gene name -> Gene description
 - PROTEIN DOMAINS -> Protein features -> transmembrane helices start & end
- Click on “Count” and “Results”. There are 107 genes with “GPCR, rhodopsin-like, 7TM” protein domain in *C. quinquefasciatus* genome.
- Select an output format to download.

³ IPR004117 comes back as “GPCR, rhodopsin-like, 7TM”

Sample query #4

List of orthologous genes between two species

- Go to BioMart. Choose genes as your database and *A. gambiae* as your dataset.
- Select the filters
 - Filters: multi-species comparisons ---> Homolog filters ---> Orthologous *An. albimanus*
 - Attributes:
Homologs ---> Orthologs ---> *A. albimanus* ---> gene stable ID, chromosome/scaffold, % target & % query, Ortholog confidence [0 low, 1 high]⁴
- Click on Count and Results. There are 10,069 orthologous genes between *A. gambiae* and *A. albimanus*. The file can be download to sort the genes based on the orthology confidence.

⁴ FAQ: How are "high confidence" orthologs defined?,
<https://www.vectorbase.org/faqs/how-are-high-confidence-orthologs-defined>

Sample query #5

How to join two different datasets?

BioMart queries are run against a single species database, but if you click on the lower “Dataset” link, queries can “join” a second dataset. The results of the second dataset are connected and depend on the first one.

This second dataset could be in the gene, variation or expression databases. For query #4 add *A. gambiae* variation (short variants, SNPs and INDELs) as the second dataset

3. Questions and practice exercises

Instructions: Please take note of how do you reach your answer including the specific “Filters” and “Attributes” used in each case. Use BioMart “Genes” database, to solve these exercises.

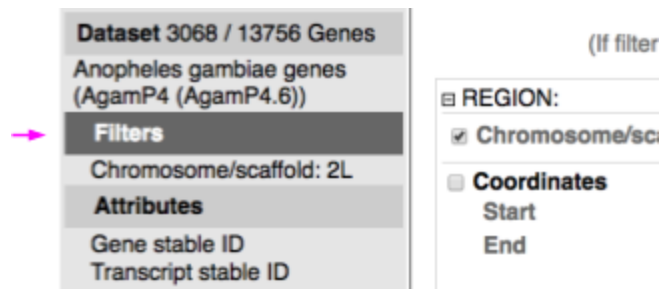

To find the number of results matching the filters you have provided, click on “Count” (see below) - to see the first few rows of the results and the attributes you have selected, click on “Results”.

a. Gene content - using “Filters”

- Choose Database: VectorBase Genes
- Choose Dataset: *Anopheles gambiae* genes
- Click on “Filters”
- Explore the different filter types by expanding and contracting each section of the form.

- How many genes are there on *An. gambiae* chromosome arm 2L?

3,069

- Modify this using the "Gene->Gene type" filter to find out how many **protein coding** genes are located in chromosome arm 2L:

2,916

- Add one more filter to find all protein coding genes are between nucleotides 9,000,000 -10,000,000 of 2L? (Hint: you can not use periods or commas, see below)

Dataset <input type="text"/> / 13763 Genes	
Anopheles gambiae genes (AgamP4)	
Filters

- To start a new session click on “New”

- Now you are going to filter your results using a list of *An. gambiae* gene IDs. Use the sample genes located in Tutorial page: VectorBase_BioMart_SampleGenes_2017.txt

You can copy-paste in the IDs (see below) or upload the file containing IDs from your computer:

- Click on “Count” and “Results”. Results are presented in a Table format. What are the (default) columns of the table?

Gene stable ID & Transcript stable ID

- Click on “New”

- Again, choose *An. gambiae* genes
- Filter using the Gene Names (symbols) OBP1, OBP2, ... OBP10
Type them in the provided box. **Hint:** See the screenshot below for guidance when using the ID list limit filter:

(If filter values are truncated in any lists, hover over the text to see the full list)

☐ Excluded

- Can you add further species? **Yes you can.** The ones available are all VectorBase genomes plus *Drosophila melanogaster*. For a list of all available genomes follow this link: <https://www.vectorbase.org/genomes>

- Start a new session. Download the splice variants in cDNA format for the gene AGAP004707

The screenshot shows the VectorBase BioMart interface. On the left, the 'Dataset 1 / 13763 Genes' section is expanded, showing 'Anopheles gambiae genes (AgamP4)'. Under 'Filters', 'Gene stable ID(s) [e.g. AGAP000002]: [ID-list specified]' is entered. Under 'Attributes', 'Gene stable ID', 'Transcript stable ID', and 'cDNA sequences' are selected. On the right, the 'Export all results to' dropdown is set to 'File', and the 'Go' button is highlighted. Below this, the 'Email notification to' field is empty. The 'View' section shows '10 rows as FASTA'. The main content area displays the cDNA sequence for AGAP004707, with the first line highlighted: '>AGAP004707 | AGAP004707-RA'.

By default, all result queries include the Gene stable ID and the Transcript stable ID, this last one has all the gene splice variants. In this case there 13 splice variants, from RA to RM.

- Come up with a meaningful query that relates to your area of interest.

If you need help with any question and its answer contact us at info@vectorbase.org. Because VectorBase data, tools and resources are updated every two months (6 release cycles per year), answers to these exercises will change too.
